16 M × 64 BIT SYNCHRONOUS DYNAMIC RAM DIMM

MB8516S064CZ-102/-103/-102L/-103L

168-pin, 4 Clock, 2-bank, based on 8 M × 8 Bit SDRAMs with SPD

■ DESCRIPTION

The Fujitsu MB8516S064CZ is a fully decoded, CMOS Synchronous Dynamic Random Access Memory (SDRAM) Module consisting of sixteen MB81F64842C devices which organized as four banks of 8 M × 8 bits and a 2K-bit serial EEPROM on a 168-pin glass-epoxy substrate.

The MB8516S064CZ features a fully synchronous operation referenced to a positive edge clock whereby all operations are synchronized at a clock input which enables high performance and simple user interface coexistence.

The MB8516S064CZ is optimized for those applications requiring high speed, high performance and large memory storage, and high density memory organizations.
This module is ideally suited for workstations, PCs, laser printers, and other applications where a simple interface is needed.

■ PRODUCT LINE & FEATURES

Parameter		MB8516S064CZ-102/-102L	MB8516S064CZ-103/-103L
CL-t_{RCD}-t_{RP}		2-2-2 clk min.	3-2-2 clk min.
Clock Frequency		100 MHz max.	100 MHz max.
Burst Mode Cycle Time		10 ns min.	10 ns min.
Output Valid from Clock		6 ns max. (CL = 2)	6 ns max. (CL = 3)
Power Dissipation	Two Banks Active	5904 mW max.	5904 mW max.
	Self Refresh Mode	57.6 mW max. (std. power) 28.8 mW max. (low power)	57.6 mW max. (std. power) 28.8 mW max. (low power)

- Un-buffered 168-pin DIMM Socket Type
  (Lead pitch: 1.27 mm)
- Conformed to JEDEC Standard (4 CLK)
- Organization: 16,777,216 words × 64 bits
- Memory: MB81F64842C (8 M × 8, 4-bank) × 16 pcs
- 3.3 V ±0.3 V Supply Voltage
- All input/output LVTTL compatible
- Conformed to Intel PC/100 spec
- 4096 Refresh Cycle every 65.6 ms
- Auto and Self Refresh
- CKE Power Down Mode
- DQM Byte Masking (Read/Write)
- Serial Presence Detect (SPD) with Serial EEPROM:
  Intel SPD spec Rev 1.2A Format
- Module size:
  1.375” (height) × 5.25” (length) × 0.157” (thickness)

*1. Voltages referenced to V_{SS} (=0V)

*2. Overshoot limit: V_{IH} (max.) = V_{CC} +1.5 V with a pulse-width ≤ 5 ns.

*3. Undershoot limit: V_{IL} (min.) = –1.5 V with a pulse-width ≤ 5 ns.

WARNING: The recommended operating conditions are required in order to ensure the normal operation of the semiconductor device. All of the device's electrical characteristics are warranted when the device is operated within these ranges.

Always use semiconductor devices within their recommended operating conditionranges. Operation outside these ranges may adversely affect reliability and could result in device failure.

No warranty is made with respect to uses, operating conditions, or combinations not represented on the data sheet. Users considering application outside the listed conditions are advised to contact their FUJITSU representatives beforehand.

Notes: *1. An initial pause (DESL on NOP) of 200 µs is required after power-up followed by a minimum of eight Auto-refresh cycles.
*2. 1.4 V or V_{REF} is the reference level for measuring timing of signals.
Transition times are measured between V_{IH} (min) and V_{IL} (max).
*3. AC characteristics assume t_T = 1 ns and 50 pF of capacitance load.
*4. Assumes t_{RCD} is satisfied.
*5. t_{AC} also specifies the access time at burst mode except for first access.
*6. Specified where output buffer is no longer driven.
*7. Actual clock count of t_{RC} (I_{RC}) will be sum of clock count of t_{RAS} (I_{RAS}) and t_{RP} (I_{RP}).
*8. Operation within the t_{RCD} (min) ensures that access time is determined by t_{RCD} (min) +t_{AC} (max) ; if t_{RCD} is greater than the specified t_{RCD} (min), access time is determined by t_{AC}.
*9. All base values are measured from the clock edge at the command input to the clock edge for the next command input.
All clock counts are calculated by a simple formula:
clock count equals base value divided by clock period (round off to a whole number).

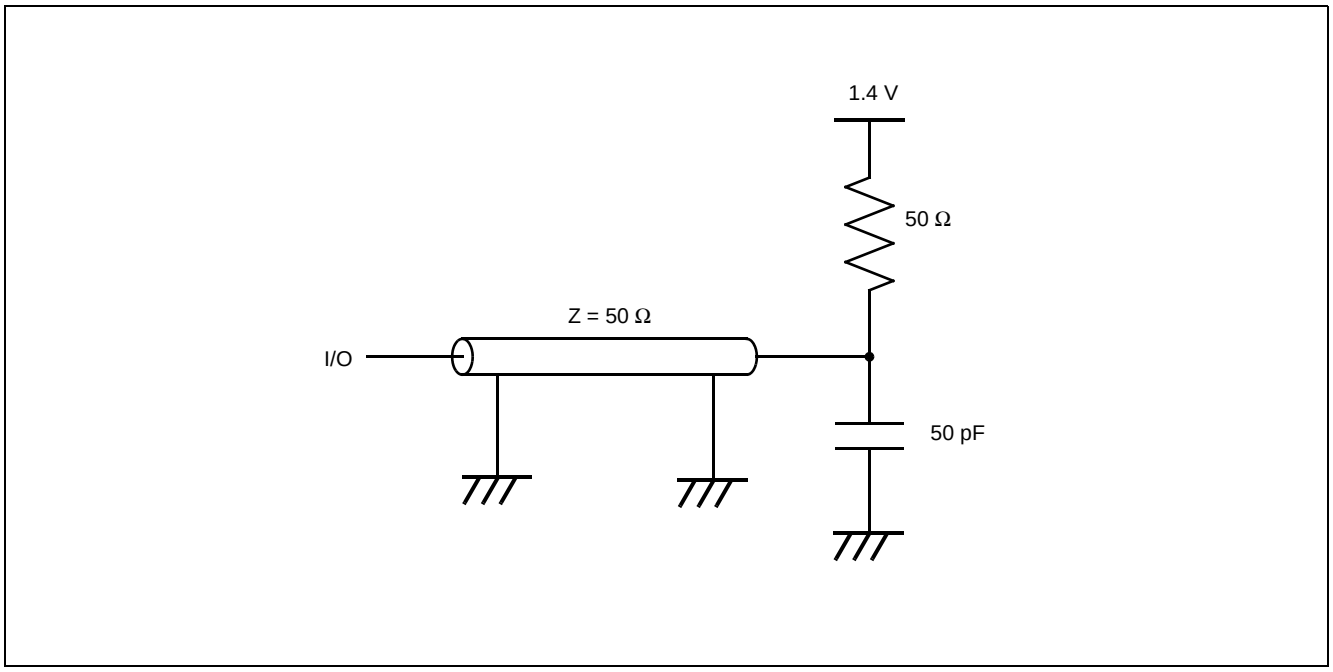
■ AC OPERATING TEST CONDITION (Example of AC Test Load Circuit)



■ SERIAL PRESENCE DETECT(SPD) FUNCTION

1. PIN DESCRIPTIONS

SCL (Serial Clock)

SCL input is used to clock all data input/output of SPD.

SDA (Serial Data)

SDA is a common pin used for all data input/output of SPD. The SDA pull-up resistor is required due to the open-drain output.

SA_0, SA_1, SA_2 (Address)

Address inputs are used to set the least significant three bits of the eight bits slave address. The address inputs must be fixed to select a particular module and the fixed address of each module must be different each other.

2. SPD OPERATIONS

CLOCK and DATA CONVENTION

Data states on the SDA can change only during SC L= Low. SDA state changes during SCL = High are indicated start and stop conditions. Refer to Fig. 1 below.

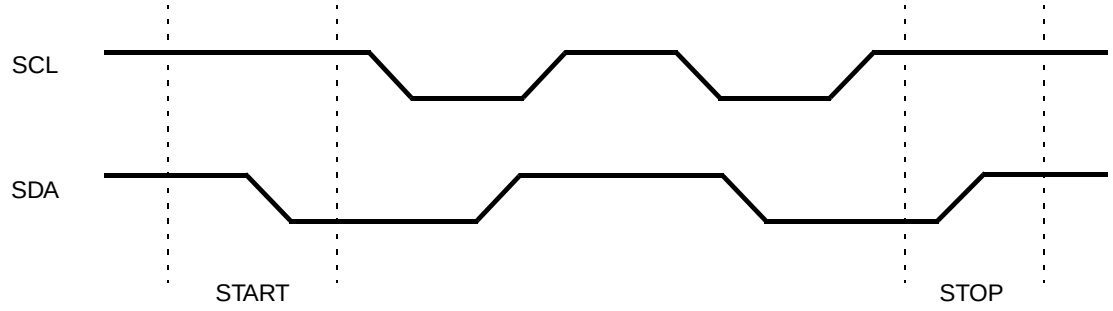
START CONDITION

All commands are preceded by a start condition, which is a transition of SDA state from High to Low when SCL = High. SPD will not respond to any command until this condition has been met.

STOP CONDITION

All read or write operation must be terminated by a stop condition, which is a transition of SDA state from Low to High when SCL = High. The stop condition is also used to make the SPD into the state of standby power mode after a read sequence.

Fig. 1 – START AND STOP CONDITIONS



START = High to Low transition of SDA state when SCL is High

STOP = Low to High transition of SDA state when SCL is High

ACKNOWLEDGE

Acknowledge is a software convention used to indicate successful data transfer. The transmitting device, either master or slave, will release the bus after transmitting eight bits. During the ninth clock cycle the receiver will put the SDA line to Low in order to acknowledge that it received the eight bits of data.

The SPD will respond with an acknowledge when it received the start condition followed by slave address issued by master.

In the read operation, the SPD will transmit eight bits of data, release the SDA line and monitor the line for an acknowledge. If an acknowledge is detected and no stop condition is issued by master, the SPD will continue to transmit data. If an acknowledge is not detected, the SPD will terminated further data transmissions. The master must then issue a stop condition to return the SPD to the standby power mode.

In the write operation, upon receipt of eight bits of data the SPD will respond with an acknowledge, and await the next eight bits of data, again responding with an acknowledge until the stop condition is issued by master.

SLAVE ADDRESS ADDRESSING

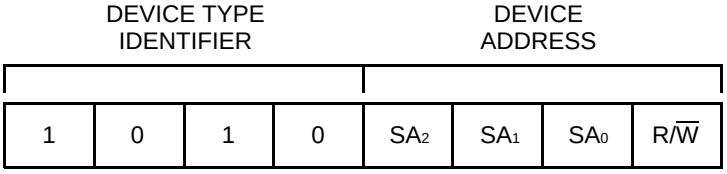
Following a start condition, the master must output the eight bits slave address. The most significant four bits of the slave address are device type identifier. For the SPD this is fixed as 1010[B]. Refer to the Fig. 2 below.

The next three significant bits are used to select a particular device. A system could have up to eight SPD devices —namely up to eight modules— on the bus. The eight addresses for eight SPD devices are defined by the state of the SA_0, SA_1 and SA_2 inputs.

The last bit of the slave address defines the operation to be performed. When R/$\overline{W}$ bit is “1”, a read operation is selected, when R/$\overline{W}$ bit is “0”, a write operation is selected.

Following the start condition, the SPD monitors the SDA line comparing the slave address being transmitted with its slave address (device type and state of SA_0, SA_1, and SA_2 inputs). Upon a correct compare the SPD outputs an acknowledge on the SDA line. Depending on the state of the R/$\overline{W}$ bit, the SPD will execute a read or write operation.

Fig. 2 – SLAVE ADDRESS

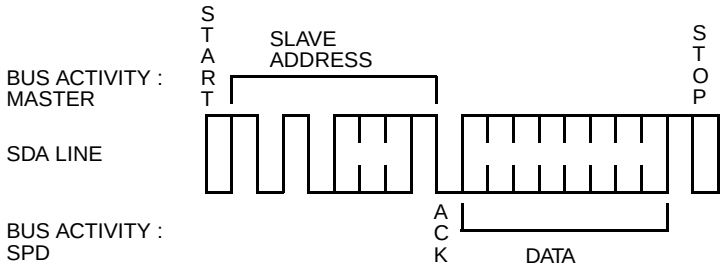


3. READ OPERATIONS

CURRENT ADDRESS READ

Internally the SPD contains an address counter that maintains the address of the last data accessed, incremented by one. Therefore, if the last access (either a read or write operation) was to address(n), the next read operation would access data from address(n+1). Upon receipt of the slave address with the R/$\overline{W}$ bit = "1", the SPD issues an acknowledge and transmits the eight bits of data during the next eight clock cycles. The master terminates this transmission by issuing a stop condition, omitting the ninth clock cycle acknowledge. Refer to Fig. 3 for the sequence of address, acknowledge and data transfer.

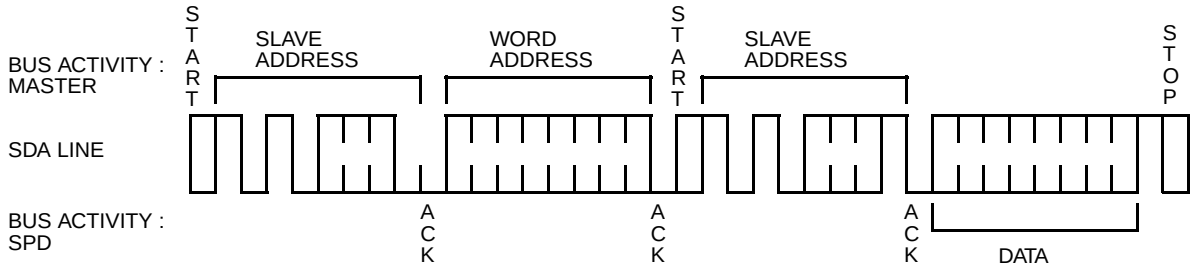
Fig. 3 – CURRENT ADDRESS READ



RANDOM READ

Random Read operations allow the master to access any memory location in a random manner. Prior to issuing the slave address with the R/$\overline{W}$ bit = "1", the master must first perform a "dummy" write operation on the SPD. The master issues the start condition, and the slave address followed by the word address. After the word address acknowledge, the master immediately reissues the start condition and the slave address with the R/$\overline{W}$ bit = "1". This will be followed by an acknowledge from the SPD and then by the eight bits of data. The master terminates this transmission by issuing a stop condition, omitting the ninth clock cycle acknowledge. Refer to Fig. 4 for the sequence of address, acknowledge and data transfer.

Fig. 4 – RANDOM READ



SEQUENTIAL READ

Sequential Read can be initiated as either a current address read or random read. The first data are transmitted as with the other read mode, however, the master now responds with an acknowledge, indicating it requires additional data. The SPD continues to output data for each acknowledge received. The master terminates this transmission by issuing a stop condition, omitting the ninth clock cycle acknowledge. Refer to Fig. 5 for the sequence of address, acknowledge and data transfer.

The data output is sequential, with the data from address(n) followed by the data from address(n+1). The address counter for read operations increments all address bits, allowing the entire memory contents to be serially read during one operation. At the end of the address space (address 255), the counter “rolls over” to address 0 and the SPD continues to output data for each acknowledge received.

FUJITSU semiconductor devices are intended for use in standard applications (computers, office automation and other office equipment, industrial, communications, and measurement equipment, personal or household devices, etc.).

CAUTION:
Customers considering the use of our products in special applications where failure or abnormal operation may directly affect human lives or cause physical injury or property damage, or where extremely high levels of reliability are demanded (such as aerospace systems, atomic energy controls, sea floor repeaters, vehicle operating controls, medical devices for life support, etc.) are requested to consult with FUJITSU sales representatives before such use. The company will not be responsible for damages arising from such use without prior approval.

Any semiconductor devices have an inherent chance of failure. You must protect against injury, damage or loss from such failures by incorporating safety design measures into your facility and equipment such as redundancy, fire protection, and prevention of over-current levels and other abnormal operating conditions.
