## DC-coupled vertical deflection circuit

## TDA8351

## FEATURES

- Few external components
- Highly efficient fully DC-coupled vertical output bridge circuit
- Vertical flyback switch
- Guard circuit
- Protection against:
  - short-circuit of the output pins (7 and 4)
  - short-circuit of the output pins to  $V_P$
- Temperature (thermal) protection
- High EMC immunity because of common mode inputs
- A guard signal in zoom mode.

## GENERAL DESCRIPTION

The TDA8351 is a power circuit for use in 90° and 110° colour deflection systems for field frequencies of 50 to 120 Hz. The circuit provides a DC driven vertical deflection output circuit, operating as a highly efficient class G system.

## Note

1. A flyback supply voltage of >50 V up to 60 V is allowed in application. A 220 nF capacitor in series with a 22  $\Omega$  resistor (dependent on  $I_O$  and the inductance of the coil) has to be connected between pin 7 and ground. The decoupling capacitor of  $V_{FB}$  has to be connected between pin 6 and pin 3. This supply voltage line must have a resistance of 33  $\Omega$  (see application circuit Fig.6).

## FUNCTIONAL DESCRIPTION

The vertical driver circuit is a bridge configuration. The deflection coil is connected between the output amplifiers, which are driven in phase opposition. An external resistor ( $R_M$ ) connected in series with the deflection coil provides internal feedback information. The differential input circuit is voltage driven. The input circuit has been adapted to enable it to be used with the TDA9150, TDA9151B, TDA9160A, TDA9162, TDA8366 and TDA8376 which deliver symmetrical current signals. An external resistor ( $R_{CON}$ ) connected between the differential input determines the output current through the deflection coil. The relationship between the differential input current and the output current is defined by:  $I_{diff} \times R_{CON} = I_{coil} \times R_M$ . The output current is adjustable from 0.5 A (p-p) to 3 A (p-p) by varying  $R_M$ . The maximum input differential voltage is 1.8 V. In the application it is recommended that  $V_{diff} = 1.5$  V (typ). This is recommended because of the spread of input current and the spread in the value of  $R_{CON}$ .

The flyback voltage is determined by an additional supply voltage  $V_{FB}$ . The principle of operating with two supply voltages (class G) makes it possible to fix the supply voltage  $V_P$  optimum for the scan voltage and the second supply voltage  $V_{FB}$  optimum for the flyback voltage. Using this method, very high efficiency is achieved.

The supply voltage  $V_{FB}$  is almost totally available as flyback voltage across the coil, this being possible due to the absence of a decoupling capacitor (not necessary, due to the bridge configuration). The output circuit is fully protected against the following:

- thermal protection
- short-circuit protection of the output pins (pins 4 and 7)
- short-circuit of the output pins to  $V_P$ .

A guard circuit  $V_{O(guard)}$  is provided. The guard circuit is activated at the following conditions:

- during flyback
- during short-circuit of the coil and during short-circuit of the output pins (pins 4 and 7) to  $V_P$  or ground
- during open loop
- when the thermal protection is activated.

This signal can be used for blanking the picture tube screen.

**Notes**

- A flyback supply voltage of >50 V up to 60 V is allowed in application. A 220 nF capacitor in series with a 22 Ω resistor (dependent on I<sub>O</sub> and the inductance of the coil) has to be connected between pin 7 and ground. The decoupling capacitor of V<sub>FB</sub> has to be connected between pin 6 and pin 3. This supply voltage line must have a resistance of 33 Ω (see application circuit Fig.6).
- The linearity error is measured without S-correction and based on the same measurement principle as performed on the screen. The measuring method is as follows:  
Divide the output signal I<sub>4</sub> - I<sub>7</sub> (V<sub>RM</sub>) into 22 equal parts ranging from 1 to 22 inclusive. Measure the value of two succeeding parts called one block starting with part 2 and 3 (block 1) and ending with part 20 and 21 (block 10). Thus part 1 and 22 are unused. The equations for linearity error for adjacent blocks (LEAB) and not adjacent blocks (NAB) are given below  

$$\text{LEAB} = \frac{a_k - a_{(k+1)}}{a_{\text{avg}}}; \quad \text{NAB} = \frac{a_{\text{max}} - a_{\text{min}}}{a_{\text{avg}}}$$
- Referenced to V<sub>p</sub>.
- V values within formulae, relate to voltages at or between relative pin numbers, i.e. V<sub>7-4</sub>/V<sub>1-2</sub> = voltage value across pins 7 and 4 divided by voltage value across pins 1 and 2.
- V<sub>9-4</sub> AC short-circuited.
- Frequency response V<sub>7-4</sub>/V<sub>9-4</sub> is equal to frequency response V<sub>7-4</sub>/V<sub>1-2</sub>.
- At V<sub>(ripple)</sub> = 500 mV eff; measured across R<sub>M</sub>; f<sub>i</sub> = 50 Hz.

**SOLDERING****Plastic single in-line packages**

BY DIP OR WAVE

The maximum permissible temperature of the solder is 260 °C; this temperature must not be in contact with the joint for more than 5 s. The total contact time of successive solder waves must not exceed 5 s.

The device may be mounted up to the seating plane, but the temperature of the plastic body must not exceed the

specified storage maximum. If the printed-circuit board has been pre-heated, forced cooling may be necessary immediately after soldering to keep the temperature within the permissible limit.

**REPAIRING SOLDERED JOINTS**

Apply the soldering iron below the seating plane (or not more than 2 mm above it. If its temperature is below 300 °C, it must not be in contact for more than 10 s; if between 300 and 400 °C, for not more than 5 s.
