AM Tuner System for Car Radios and Home Stereos

Overview

The LA1135 is a high-performance AM electronic tuner IC that is greatly improved in cross modulation characteristics. It is especially suited for use in car radio and home stereo (antenna: loop) applications.

Functions

- MIX
- OSC (with ALC)
- IF amplifier
- Detector
- AGC (normal)
- RF wide-band AGC
- Auto search stop signal (signal meter output)
- Local oscillation buffer output
- Others

Features

- Excellent cross modulation characteristics: Meets the requirements for preventing not only adjacent-channel interference but also interference caused by all channels within broadcast band.
- Narrow-band signal meter output: Usable as auto search stop signal. Has linearity up to 80 dB μ .
- Local oscillation buffer output: Facilitates designing of electronic tuner system, frequency display, etc.
- OSC (with ALC): Improves tracking error because oscillation output is stabilized at a low level (380 mVrms) for varactor diode.
- MIX: Double-balanced differential MIX meeting the requirements for preventing spurious interference, IF interference.
- Good characteristics at high input: 130 dB μ input
 $f_m = 400$ Hz 80% mod THD = 0.4% typ
- Low noise: Good S/N at medium input (56 dB typ)
- Usable sensitivity: (S/N = 20 dB input): 25 dB μ (2SK315
 $I_{DSS} = 11$ mA)
- V_{CC} variation compensation: Less variation in gain, distortion: 8 to 12 V
- Reduced pop noise: Capable of reducing pop noise at the time of V_{CC} ON, mode select by adjusting AGC time constant.

Package Dimensions

Proper cares in using IC

1. Bias condition: $RF V_{CC} \cong IF V_{CC}$
2. Avoid coupling between the antenna tuning circuit and the local oscillation.
3. Connect detection capacitor C15 across pins 13 (output) and 14 (V_{CC}) so that no leakage of the IF signal to the GND line occurs. (If connected to GND, the tweet and the usable sensitivity may get worse.) Radiation from C15 may cause harmonics in the IF signal to return to the RF stage, thereby leading to more tweet interference. So, connect C15 as close to pins 13, 14 as possible. Consider the direction of the capacitor and separate it from the ANT circuit.
4. For R9, use a semifixed resistor with V_{SM} considered.
5. When designing the coils, consider the following conditions.
Shown below is the input level at each pin at which the detection output at $f_m = 400$ Hz 30% mod becomes -25 dB.

ANT	MIX	IF	Det
16.0	28.0	45.0	61.0

(dB μ)

How to apply input to each stage

6. ANT damping
To make the ANT damping constant within the receiving band, change the application circuit as shown below.

Measures

- Replace R1 with C_D .
- C_D (2000 pF to 3000 pF or thereabouts)
- Relocate L2.
- Damping (600 kHz to 1400 kHz) Old circuit -15 dB
New circuit -4 dB

LA1135, 1135M

7. Meaning of L2

If the RF stage is double-tuned, the difference in sensitivity within the RF band almost disappears, but an antiresonance point of approximately 20 MHz appears, thereby leading to worse spurious characteristics. So, L2 is used to remove the SW band.

8. Wide-band AGC

This IC contains 2-channel wide-band AGC. Pin 6 detects an undesired signal within the RF band and wide-band AGC is applied. This detection sensitivity is determined inside the IC. Pin 2 detects an undesired signal outside the RF band. This detection sensitivity is determined by R3. When 1 mVrms (f = 1 MHz) signal is applied to pin 2, AGC operates.

9. Measures against suppression of sensitivity

In the AGC circuit of the test circuit the presence of an undesired signal of high strength within the receiving band may cause the desired signal to be suppressed when the desired signal is low or medium in strength. Shown below is the circuit configuration where the necessary measures are taken against this suppression.

10. Transient response of S meter output at search, stop mode

The circuit configuration shown below is available to stabilize the transient response of the S meter output at the search, stop mode.

11. When using LW (approximately 50°C or greater), additionally connect a resistor of 27 kΩ across pins 18 and 19 against increase in local oscillation level. When using MW, no additional resistor is required.

12. Improvement in image frequency interference

Change the RF double-tuning coil as follows, and the image frequency interference becomes 63 dB at $f_i = 1400 \text{ kHz}$. (Q of the tuning circuit must not be decreased with resistor 100 kΩ.)

Unit (resistance: Ω , capacitance: F)

Specification for coil

	YT-30202(Mitsumi)	2157-2239-649 (Sumida)
1-3	84T	7BRS-9286A (Toko)
4-6	17T	

- The variations (especially in case of small coupling coefficient) in the oscillation coil may cause a parasitic oscillation of approximately 100 MHz to occur at the local oscillation buffer output (pin 20) at low temperatures. In this case, connect a capacitor of 30 pF or greater across pin 20 and GND. (When the oscillation coil is used with no tap, no problem arises.)
- The recommended double-tuning circuit has a loose coupling at 2T. Therefore, the change in the total number of turns may affect the coupling coefficient subtly, causing a tight coupling and making the selectivity characteristic double-humped. Especially for a receiving band of 1400 kHz or more, the tracking method may affect the band characteristic of sensitivity and the cross modulation characteristic considerably. When making a design, check to see if critical coupling occurs or not.
- Sensitivity difference at 600 kHz or less

In the application circuit configuration shown below, the bypass capacitor in the position where the tuning voltage is applied and coupling L for double-tuning may cause an antiresonance point of 400 kHz to 600 kHz depending on the variations in the coil, varactor diode, etc. The value of the bypass must be 0.047 μ F or greater. The recommended value is 0.1 μ F.

Unit (resistance: Ω , capacitance: F)

16. Measure against suppression of sensitivity in the presence of an undesired signal of high strength
(Sample application where two PIN diodes are used in the antenna damping circuit)

The LA1135 contains the wide-band AGC circuit (wide-band AGC with pin 2 input) against cross modulation which occurs because an undesired signal of high strength distorts the FET input. The AGC = ON level depends on the value of external resistor R3 as shown below.

When a nonlinear element, such as transistor, is used for antenna damping, cross modulation which occurs when the transistor is turned ON is as shown below.

Unit (resistance: Ω , capacitance: F)

The dynamic range of the FET input covers up to approximately 110 dB μ of antenna input, but the AGC-ON level must be set lower because of the bad effect shown above.

Therefore, there are some cases where it is difficult to receive a desired signal of low strength in the presence of an undesired signal of high strength. To solve this problem, a sample application circuit where two PIN diodes with good linearity are used for antenna damping and its cross modulation characteristic are shown below.

Sample Application Circuit where two PIN diodes are used for ANT damping

Unit (resistance: Ω , capacitance: F)
